See attached

Samples A, E and F (good protocol; WGAgood) have a different pattern than samples B, C and D (bad lysis; WGSbad).

The background levels are very variable in these samples, as these were done with different conditions.

Effectively, I saw that in the TCR samples that I have so far, both background signatures occur (when doing signature assignment using mSigAct), see below

I also included those vcfs in case you want to take a look

Signature assignment (counts)
